## **Commuter Rail Transit and Economic Development**

### **Abstract**

Commuter rail transit (CRT) is a form of rail passenger service connecting downtowns and other major activity centers with suburban commuter towns and beyond. Between 1834 and 1973, only three public CRT systems were built in the U.S. serving New York, Chicago and then Boston. There are now 25 such systems. Modern CRT systems aim to expand economic development in metropolitan areas. But do they? This article evaluates the economic development performance of five modern CRT systems built in the South and West: “Tri Rail” connecting the metropolitan areas of Miami and West Palm Beach, Florida; “Rail Runner” connecting the metropolitan areas of Albuquerque and Santa Fe, New Mexico; “FrontRunner” connecting the metropolitan areas of Ogden and Salt Lake City, Utah; “Coaster” serving metropolitan San Diego; and “Sounder” connecting the metropolitan areas of Tacoma and Seattle. For all metropolitan areas combined, areas within 0.50 mile of CRT stations lost share in the change of jobs. All CRT station areas gained share of jobs in the office and health care economic groups, and most gained share in the knowledge economic group. All CRT station areas lost share of jobs in manufacturing, and nearly all lost share in the retail-lodging-food service economic group. Yet, station areas served by the FrontRunner CRT system gained share of jobs overall as well for nearly all economic groups. Planning and policy implications are offered.

## **Introduction**

Commuter rail transit (CRT) is a form of rail passenger service connecting downtowns and other major activity centers with suburban and exurban places. Historically, CRT systems connected distant suburbs with downtowns in the northeast and Great Lakes regions, serving mostly affluent business people working in downtowns. In *The Exurbanites*, for instance, August Spector (1955) chronicled the lifestyles of families who lived in Bucks County, Pennsylvania but whose breadwinners commuted daily to work through New Jersey into midtown or downtown Manhattan via privately operated railroads. Amtrak now provides those longer-distance commuter services, notably between Boston and Washington, DC.

In recent years, commuter rail service has been introduced to metropolitan areas in the South and West. One implicit purpose of these systems is to generate economic development especially around commuter rail stations. But there is scant empirical analysis of whether and the extent to which commuter rail stations are associated with economic development. Based on analysis of five commuter rail systems, this article explores the connection between CRT systems and economic development around CRT stations. It begins with an overview of commuter rail transit including its role in facilitating economic development; presents the research design, analytic approach, data and study areas; reports results with interpretations; and offers overall implications for CRT planning and economic development.

## **Overview of Commuter Rail Transit and its Relation to Economic Development**

The nation's first public commuter rail service was launched in 1834: the Metropolitan Transit Authority's Long Island Rail Road connecting Long Island with Manhattan Island, New York. Nearly 70 years later, the nation's second public commuter rail service started (in 1903)

connecting South Bend, Indiana with Chicago. It took nearly another 70 years (1973) before the nation's third public commuter rail service was launched, connecting Boston with its suburbs. Since 1983, another 22 public CRT systems have been initiated. Table 1 shows key features of all public systems in place as of 2013.

CRT service areas extend 10 to 100 miles from downtowns, traveling at speeds from about 30 to more than 100 miles per hour. According to the American Public Transit Association (APTA 2015), the average trip was nearly 25 miles in 2013 or about five times the distance of light rail passengers. Because of longer travel distances and travel times, CRT cars offer more seating options than light rail, and often with Wi-Fi, food and beverage services. Most CRT lines run along commercial rails, by agreement with commercial carriers. They are also driven by diesel engines though occasionally with electrical drive trains.

While the chief function of CRTs is to connect workers living in suburban and exurban areas to their workplaces, literature suggests that a collateral purpose can be to advance economic development at CRT stations (APTA, 1997; Ayvalik and Khisty, 2002; Deka and Marchwinski, 2014; Kennedy, 2002; Seskin, Cervero and Zupan, 1996). CRT systems tend to run along major transportation corridors. A key impetus for their construction is to lessen congestion along highways, and in doing so facilitate agglomeration economies of downtowns and other employment centers (Boarnet and Haughwout, 2000; Ciccone and Hall, 1996; Glaeser, 2011; Voith, 1998). But there is scant research into the connection between CRT systems and economic development, especially outside downtowns. One view is that CRT systems are an under-utilized economic development strategy especially in moderate and smaller metropolitan areas outside the densely developed areas of the Northeast and Great Lakes regions. To test this assertion, five CRT systems in the South and West are analyzed, as described below.

**Table 1. Summary of U.S. Commuter Rail Systems**

Rank	System	Major cities served	Annual Ridership (2013)	Ave. Weekday Ridership (Q4 2013)	Route miles	Ridership per mile (Q4 2013)	Lines	Stations	Year Opened
1	MTA Long Island Rail Road	New York	97,090,300	334,100	335.9	994.6	11	124	1834
2	MTA Metro-North Railroad	New York	83,326,200	298,700	329.6	777.9	5	121	1983
3	New Jersey Transit Rail	New York / Philadelphia	81,942,000	302,500	398.2	758.4	11	164	1983

Source: Adapted from [http://en.wikipedia.org/wiki/List\\_of\\_United\\_States\\_commuter\\_rail\\_systems\\_by\\_ridership](http://en.wikipedia.org/wiki/List_of_United_States_commuter_rail_systems_by_ridership)

Economic development can be measured in many ways, employment change being one of them. The focus of this article is to estimate the extent to which there is a link between CRT stations and employment change over time. Theoretically, areas proximate to commuter rail stations should have much better accessibility. By reducing the effects of congestion, CRT systems should abet the preservation of existing agglomeration economies and the creation of new ones. Without the diseconomies of congestion, existing employment clusters should continue to grow, and the relative concentration of employment within clusters served by a CRT should continue to increase.

Secondly, CRT systems may benefit certain economic sectors but not others. In their recent study of employment within one-half mile of transit stations serving 34 transit systems, Belzer, Srivastava and Austin (2011) found that while jobs increase in the arts, entertainment, and recreation sector as well as the food and accommodation, and health care and social assistance sectors, they fell in the manufacturing sector. They also found that public administration had the greatest share of jobs found near transit stations. Several other sectors also concentrated around transit stations such as professional, scientific, and technical services, and retail. On the other hand, as a whole the station areas experienced declining shares of jobs relative to their regions, with the exception of jobs in the utilities, information, and the arts, entertainment, and recreation sectors. Belzer, Srivastava and Austin surmised that much of the metropolitan job growth continues to favor auto-oriented locations. Their study did not report results for individual systems or even types of systems. Also, with a study period from 2002 to 2008, it did not include the Great Recession. In sum, there is no research directly linking CRT to economic development. This article builds on prior research with special reference to CRT systems and economic development.

## **Research Design, Analytic Approach, Data and Study Areas**

The research question is:

*Do areas within 0.50 miles of CRT stations (“station areas”) gain share of regional change in jobs over time overall and with respect to economic sectors combined into economic groups?*

As the research question addresses change over time, a longitudinal quasi-experimental study design is appropriate. Further, as the research question addresses change in jobs within CRT station areas compared the region, shift-share analysis is a reasonable analytic approach the details of which will be described below.

Because the research question requires small-area data on jobs disaggregated to economic sectors, the appropriate source of data is the Longitudinal Employee-Household Dynamics (LEHD) database, which is available annually for most metropolitan areas at the census block level since 2002. LEHD data are collected in 20 economic sectors defined by the North American Industrial Classification System (NAICS). Only those sectors that involve occupying physical spaces are considered, meaning that the two natural resources sectors and the construction sector are removed from analysis. The remaining 17 sectors are combined into eight economic groups in the manner shown in Table 2.

**Table 2**  
**Combinations of NAICS Sectors into Economic Groups for Analysis**

<b>NAICS Code</b>	<b>NAICS Sector Title and Economic Group Name</b>

*Source:* Adapted from the North American Industrial Classification System.

The study areas were selected as follows. They should be in growing areas so that the attractiveness of CRT station areas can be reasonably detected. Metropolitan areas in the South and West census regions lend themselves to this first filter. CRT systems should also be sufficiently large, measured in ridership, to also generate reasonably detectible results; more than one million riders in 2013 are selected as the second filter (see Table 1). Finally, CRT systems selected for analysis should not be within very large metropolitan areas that have multiple transit systems as size and variety of transit options can complicate analysis. The final filter thus rules out the top 10 largest combined statistical areas. The study areas selected for this analysis include the following, arrayed clockwise from southeast to northwest:

- Tri Rail serving the metropolitan areas of Miami, Ft. Lauderdale and Palm Beach, Florida;
- Rail Runner serving the metropolitan areas of Albuquerque and Santa Fe, New Mexico, and the counties between them;
- FrontRunner serving the Salt Lake City combined statistical area and the Ogden metropolitan area, Utah;
- Coaster serving metropolitan San Diego; and
- Sounder serving the Seattle combined statistical area

Images 1 through 5 illustrate the routes of these CRT systems. Key features of each study area will be described in the results and interpretations section.

Shift-share analysis, the method used to guide the overall analytic approach, assigns the change or shift in the number of jobs with respect to the region, other economic sectors, and the local area. The “region” can be any level of geography and is often the nation or the state. In this case, the regions are the study areas described above. The ‘local’ area is often a city or county or

even state but it can be any geographic unit that is smaller than the region. In this study, it is the station areas within 0.50 miles of the nearest CRT station. This is called the “CRT station area.” As shifts in the share of jobs may vary by sector over time because of changes in economic sector mixes there is also an “industry mix” adjustment that are called “sector mix”. Adapting notations by the Carnegie Mellon Center for Economic Development (no date), the shift-share formula is used in this analysis is as follows:

$$SS_i = MA_i + SM_i + CRT_i$$

Where

$SS_i$  = Shift-Share

$RA_i$  = Regional Area share

$SM_i$  = Sector Mix

$CRT_i$  = CRT station area shift

The Regional Area (MA) share measures by how much total employment in a CRT station area changed because of change in the metropolitan area economy during the period of analysis. If metropolitan area employment grew by 10 percent during the analysis period, then employment in the CRT station area would have also grown by 10 percent. The Sector Mix (SM) identifies fast growing or slow growing economic sectors in a CRT station area based on the metropolitan area growth rates for the individual economic sectors. For instance, a CRT station area with an above-average share of the metropolitan area’s high-growth sectors would have grown faster than a CRT station area with a high share of low-growth sectors. The CRT station area shift, also called the “competitive effect”, is the most relevant component. It identifies the portion of the change in jobs attributable to characteristics of the local area (station area). A leading sector is one where that sector’s CRT station area growth rate is greater than its

metropolitan area growth rate. A lagging sector is one where the sector's CRT station area growth rate is less than its metropolitan area growth rate.

The equations for each component of the shift-share analysis are:

$$RA = ({}_iCRT \text{ station area}_{t-1} \cdot RA_t / RA_{t-1});$$

$$SM = [({}_iCRT \text{ station area}_{t-1} \cdot {}_iRA_t / {}_iRA_{t-1}) - RA]; \text{ and}$$

$$CRT = [{}_iCRT \text{ station area}_{t-1} \cdot ({}_iCRT \text{ station area}_t / {}_iCRT \text{ station area}_{t-1} - {}_iRA_t / {}_iRA_{t-1})].$$

Where:

${}_iCRT \text{ station area}_{t-1}$  = number of jobs in the CRT station area sector (i) at the beginning of the analysis period (t-1);

${}_iCRT \text{ station area}_t$  = number of jobs in the CRT station area in sector (i) at the end of the analysis period (t);

$RA_{t-1}$  = total number of jobs in the regional area at the beginning of the analysis period (t-1);

$RA_t$  = total number of jobs in the regional area at the end of the analysis period (t);

${}_iRA_{t-1}$  = number of jobs in the regional area in sector (i) at the beginning of the analysis period (t-1); and

${}_iRA_t$  = number of jobs in the regional area in sector (i) at the end of the analysis period (t).

The study period extends from 2002 through 2011, the latest year for which data were available for the analysis. Future research may update the study period. The study period extends from just after the recession of the early 2000s through the Great Recession and into recovery.

Results and interpretations are presented next.

## **Results and Interpretations**

Results and interpretations are presented for each CRT system and for all CRT systems as a whole. Descriptions of each CRT system are also included for context.

### ***Tri Rail***

Tri Rail is a heavy rail rapid transit system that opened in 1984. It is the oldest system included in this analysis. At the time of analysis, it had 70 miles of track along a freight rail corridor with 19 park and ride stations. The corridor was intended as congestion relief for the parallel I-95 corridor. It has gradually added several additional stations over the past few years. As a commuter rail system, its length is extensive as it connects multiple metropolitan areas running along the narrow strip of land between the Atlantic Ocean and Lake Okeechobee, traversing the three metropolitan areas of Miami, Ft. Lauderdale, and Palm Beach. Table 3 reports descriptive changes over the period from 2002 through 2011 as well as shift-share results for each economic group and all jobs. Figure 1 illustrates the CRT station area share of shift in jobs by economic group.

Overall, CRT station areas lost share of the change of jobs in the region. Losses in share of jobs were especially large among the manufacturing, light industrial and retail-lodging-food economic groups. In other words, the rest of the region gained shares of jobs in these economic groups. One reason may be that low-value and land-extensive manufacturing and light industrial activities are outbid for locations near CRT stations. Why the retail-lodging-food economic group would lose share is not entirely clear.

On the other hand, the CRT station areas gained important regional shares of jobs in the knowledge, office, education, and health economic groups. It is important to note that the Tri-Rail system has stops at or near major government and education centers; indeed, the system was designed to access these kinds of centers.

### ***Rail Runner***

The Rail Runner runs along a 97 mile corridor from south of Albuquerque to Santa Fe. It began with 3 stations in 2006 and was expanded to 13 stations by 2013(see Figure 2). Only the stations operating during the study period are used. It was developed as part of an ongoing project to connect Albuquerque with Santa Fe and relieve congestion along I-25, and almost more of a regional rail system than a commuter rail, requiring over two hours of travel from one end to the other. It makes use of existing freight rail right of way, and consists largely of single track with passing sidings. Descriptive changes and shift-share results are reported in Table 4 while Figure 2 illustrates results for shift-share analysis.

Compared to the study area region, CRT stations along Rail Runner lost share of jobs overall and in nearly all the economic groups during the study period. For the most part, it appears that not only do the rails run mostly through industrial or otherwise undevelopable areas, stations were not located to maximize access to existing employment areas or perhaps even to stimulate new development.

Figure 2  
 Shift-Share Analysis for Rail Runner CRT, 2002-2011

## ***FrontRunner***

The Utah Transit Authority's Front Runner commuter rail system started operations in 2005. It has since been extended to almost double its length. Only the initial segment between downtown Ogden and downtown Salt Lake City is used in the analysis, as only it was operating through the study period. The study corridor thus has 8 stations along 42 miles of track. The corridor was intended as congestion relief for the parallel I-15 corridor. Though it is the newest system studied, the local market was fully knowledgeable of the planning and investment since at least 2002.

As revealed throughout this analysis, the FrontRunner CRT systems is the only one in which realized positive net increase in share of jobs relative to its region (see Table 5 and Figure 3). It also enjoyed positive share in the shift of regional jobs in all economic groups except manufacturing and retail-lodging-food. For its part, as manufacturing operations tend to require substantial areas of land, they will often be outbid for locations near transit stations.

The largest gain in the share of regional jobs is with respect to the office economic group. As part of its station area planning, the Utah Transit Authority (UTA), operator of the CRT system, worked with local governments to assure that station areas had land use designations that allowed a mix of land uses, notably offices. Station area plans also included residential development, analysis of which is the subject of future work.

A key element of economic development success near FrontRunner CRT stations are public-private partnerships between the UTA and developers/investors. To build CRT stations, the UTA acquired large tracts of land. Surplus land is used as an incentive to facilitate economic development around CRT stations.

Figure 3  
 Shift-Share Analysis for FrontRunner CRT, 2002-2011

## *Coaster*

The Coaster is a commuter rail service that operates in the central and northern coastal regions of San Diego County, California. The service is operated by TransitAmerica Services through a contract with North County Transit District (NCTD). The Coaster has 8 stations along 41 miles of track. It serves substantially commuter needs and runs parallel to major north-south highways, thereby reducing potential congestion. It tends to operate mostly during peak commuting times during workdays.

In many ways, the Coaster CRT systems performed the worst from an economic development perspective among all the CRT systems studied. Not only did it lose the largest share of jobs relative to its region but it lost share of jobs in nearly all economic groups, the principal exception being light manufacturing.

One interpretation is that its lack of economic development performance is by design. Stations tend to be more distant from each other and set in freight rail yards where existing land uses tend to serve freight rail services. While this is also the case in many other CRT systems, it seems especially to be the case in San Diego. Moreover, it appears to have the most restrictive operating schedule among the systems analyzed. Finally, it is not apparent that CRT station area planning encourages other than freight-rail related development in them. In a separate study, Cervero and Duncan (2002) found the same limitations and their analysis of commercial and residential property values near Coaster CRT stations.

**Table 6**  
**Descriptive Change and Shift-Share Analysis for Coaster CRT, 2002-2011**

 Shift-Share Analysis for Coaster CRT, 2002-2011

## *Souder*

Souder commuter rail is a regional rail service operated by the Burlington Northern-Santa Fe Railroad on behalf of Sound Transit serving the greater Seattle metropolitan area. Service began in 2000 and by 2013 it had 9 stations along 80 miles of track. The corridor was intended as congestion relief for the parallel I-5 corridor between Everett and Seattle.

As with nearly all the other CRT systems, Souder CRT station areas lost share regional job growth overall in nearly all economic groups (see Table 7 and Figure 5). The principal exceptions are the manufacturing and light industrial economic groups. Among the CRT systems, however, it may have the most challenging physical constraints. From Seattle northward, the tracks run parallel to Puget Sound often below steep banks upland from the water. Even where the system runs inland, it passes through substantially built-out areas and often protected landscapes such as wetlands and agricultural preserves. Like the Coaster CRT, station area planning does not appear to anticipate economic development opportunities.

Overall implications for CRT planning and economic development are addressed in the last section of this article.

## **Implications for CRT Planning and Economic Development**

Until now there has been very little analysis of the association between commuter rail transit stations and economic development. Although there are important differences between the five CRT systems studied there are also some important similarities. These similarities will be reviewed first. This will be followed by an overall comparison of the systems and then implications for converting what may be considered under-performing economic development opportunities into performing ones.

Table 8 combines the data for all systems into an overall analysis, which is illustrated in Figure 6. Bear in mind that figures in Table 8 include employment data for all systems and are not averages. Taken as a whole, these five CRT systems lost share of regional change in jobs over the study period, 2002 through 2011. Indeed, only the office economic group gained substantial share. This is similar to findings for three of the five individual CRT systems presented earlier. At first blush, CRT systems do not result in much—and may detract from—economic development at least within CRT station areas.

Table 9 suggests (illustrated in Figure 7) that CRT station area outcomes are varied for reasons that will be explored here. Three systems stand out for their lack of performance: Coaster, Rail Runner and Sounder. Google Earth inspections of CRT station areas suggests what the data confirm: most are surrounded by asphalted park-and-ride lots, older and even derelict manufacturing, light industrial, warehousing and related structures, natural development constraints such as water, wetlands, open space preserves, and other land uses or constraints that seem to inhibit economic development. It is as though CRT rail stations built by these systems were not intended to advance economic development; at least that is what the outcomes suggest. Indeed, it seems reasonable to assert based on the data and analysis that as a whole, CRT station

areas serving these three systems do not generate substantial economic development and in fact discourage it.

In contrast, two systems stand out for their positive economic development outcomes: Tri Rail and FrontRunner. Station areas for both CRT systems either lost share of regional growth or performed minimally among the manufacturing, light industrial and retail-lodging-food economic groups. They also gained share of regional job growth in all other economic groups. Overall, FrontRunner CRT station areas gained job share relative to their regions while Tri Rail CRT stations lost a small share—otherwise performance of these two systems is remarkably similar. Why?

Unlike the other three systems analyzed, the Tri Rail and FrontRunner CRT systems included station area plans geared to attracting mostly nonmanufacturing and related development. For instance, Tri Rail stations are often located at or near employment centers as well as public institutions such as government centers and higher education facilities. For their part, FrontRunner stations are closely proximate to commercial centers and have station area plans calling explicitly for office, institutional, and residential development. (Future research will address residential development in and near the station areas of all five CRT systems.) Inspection of Google Earth images confirms what the data and analysis shows: most CRT rail stations serving these systems are near employment centers, if not undergoing development within their 0.50 mile station areas. Nonetheless, Google Earth inspection also reveals that many CRT station areas are similar to those of Coaster, Rail Runner and Sounder CRT station areas for their location constraints and apparent unattractiveness to economic development.

Figure 7  
 Shift-Share Analysis for Each of Five CRT Systems, 2002-2011

Billions of dollars have been spent building these CRT systems. Tens if not hundreds of millions of dollars are spent annually operating and maintaining these systems. Yet for the most part there is very little to show from an economic development perspective. How can CRT system officials and planners unlock their economic development potential?

First of all, it may only be a matter of time before the market recognizes the strategic investment opportunities these systems present. Derelict buildings and park-and-ride lots may become opportunities for redevelopment especially through public-private partnerships (Nelson 2014). But long range planning may be needed to facilitate this. Such planning can include market studies revealing long-term opportunities, infrastructure upgrades, and the occasional acquisition of land by public development agencies.

Second, it is as though many of these CRT stations are designed with shame, being positioned behind buildings and across unattractive landscapes, and themselves nothing more than drab platforms. It is as though these are unwanted places. Planners, urban designers and architects can convert these into desired places. While train activities can seem noxious they can also seem quaint and even attractive, at least to certain market segments and land uses.

Third, the forgotten element in CRT station areas seems to be people. It is as though it is assumed that people do not want to live near trains, especially in derelict industrial areas. Perhaps most people do not want to but there is growing evidence from surveys that millions of American households would live near transit options, including CRT, if they had the opportunity and presumably if land use planning, urban design, and urban amenities addressed their preferences (see Nelson 2013).

In sum, unlocking the economic development potential of commuter rail station areas ought to be the next priority of many of America's rail transit systems.
